

MENSHOV REPRESENTATION SPECTRA

GADY KOZMA AND ALEXANDER OLEVSKIĬ

1. INTRODUCTION

1.1. The problem of representing a function f on the circle $\mathbb{T}$ by a trigonometric series

$$f(t) = \sum_{k \in \mathbb{Z}} c_k e^{ikt} \quad (1)$$

has a long history. Most of the attention has been paid to Fourier expansions, where the coefficients are derived from f using an integration process. Certainly this approach requires á priori the integrability of f and even under this assumption it does not always ensure satisfactory convergence properties.

On the other hand, D. E. Menshov [2] discovered that every $f \in L^0(\mathbb{T})$, that is any measurable function from $\mathbb{T}$ to $\mathbb{C}$, with no additional requirements, can be represented as a sum of a series (1) converging almost everywhere (a.e.). The coefficients here are obtained by a special construction which has certain freedoms (for example, one can avoid using low frequency oscillations).

This result (usually called “Menshov representation theorem”) gave rise to many further investigations, aimed to find in which directions it can be extended and improved and in which it cannot. Many interesting results on this problem were obtained by Menshov himself [3], N. Bary [6] (chap. XV), Talalyan [5], Arutyunyan [13], Kashin [9], Konyagin [14], Körner [16] and others. The reader may find a comprehensive bibliography (up to '92) in the survey [15]. We add also our recent paper [17].

1.2. One aspect of the theory is: how rich must the family of exponentials be to ensure the possibility of representation. We introduce the following

Definition 1. A set Λ of integers, $\Lambda = \{\lambda(n); \dots < \lambda(-1) < \lambda(0) < \lambda(1) < \dots\}$ is a *Menshov spectrum* if every $f \in L^0(\mathbb{T})$ admits a representation

$$f(t) = \sum_{k \in \Lambda} c_k e^{ikt} \equiv \lim_{N \rightarrow \infty} \sum_{k \in \Lambda, |k| \leq N} c_k e^{ikt} \quad (2)$$

converging a.e.

It is well known that a Menshov spectrum might be quite sparse. For example, it may have density zero. Arutyunyan proved [13] that any Λ symmetric with respect to zero and containing arbitrarily long segments of integers is a Menshov spectrum.

The first result in our paper shows that a Menshov spectra might even be lacunary, that is satisfy the condition

$$\lambda(n+1) - \lambda(n) \rightarrow \infty \quad (|n| \rightarrow \infty)$$

and the sizes of the gaps may grow quite fast.

Theorem 1. *Given a positive sequence $\epsilon(n) = o(1)$ as $n \rightarrow \infty$, one can define a symmetric Menshov spectrum Λ such that*

$$\frac{\lambda(n+1)}{\lambda(n)} > 1 + \epsilon(n) \quad n = 1, 2, \dots \quad (3)$$

This result is sharp: the $\epsilon(n)$ on the right hand side cannot be replaced by a positive constant, which would mean that Λ is lacunary in the sense of Hadamard. Indeed, it is well known that if for such a Λ the series (2) converges then f must satisfy some special properties, see for example [6] (chap. XI) or [4] (chap. V).

1.3. These restrictions on the sizes of the gaps are far from giving a complete picture. The arithmetics of the set play a crucial role as well. It is obvious, for example, that $\Lambda = 2\mathbb{Z}$ is not a Menshov spectrum since the sum (2) has in this case a period $< 2\pi$. Somewhat more delicate arguments show that the set $\Lambda = \{\pm k^2\}$ is not a Menshov spectrum, even after any bounded perturbation. On the other hand, we prove the following:

Theorem 2. *For any sequence $w(k) \rightarrow \infty$ as $k \rightarrow \infty$ one can construct a symmetric Menshov spectrum Λ ,*

$$\Lambda = \{\pm k^2 + o(w(|k|))\} \quad . \quad (4)$$

We do not know whether such a result for cubes is true.

1.4. Consider now the case when *only positive* frequencies are involved. For obvious reasons this situation can be referred to as “analytic”: having a decomposition (2) with $\Lambda = \mathbb{Z}^+$ one can consider an analytic function in the unit disc

$$F(z) = \sum_{k>0} c_k z^k \quad .$$

At any point $t \in \mathbb{T}$ where the sum (2) converges, according to the classical Abel theorem, $F(z) \rightarrow f(t)$ when z approaches the point e^{it} non-tangentially. The Lusin-Privalov uniqueness theorem, see for example [10], says that “non-tangential boundary values” of an analytic function can not be an arbitrary function, specifically, if it vanishes on a set of positive measure then it is identically zero. It is interesting that for *radial* limits a.e. there are no such limitations: Kahane and Katznelson [8] proved that any measurable function f might be represented in such a form.

So the argument above leads us to the conclusion that $\mathbb{Z}^+$ *is not a Menshov spectrum*.

It turns out, however, that if we relax a bit the notion of convergence, by replacing pointwise convergence with convergence in L^0 metric, we might again get an unrestricted representation theorem

Theorem 3. *Every $f \in L^0(\mathbb{T})$ can be represented as a sum*

$$f(t) = \sum_{k>0} c_k e^{ikt} \quad (5)$$

converging in measure.

It should be mentioned that Menshov [3] showed that using convergence in measure one may get a representation (1) even for functions $f : \mathbb{T} \rightarrow \mathbb{R} \cup \{\pm\infty\}$.

Theorem 3 is also valid for such functions, so it gives a direct improvement of Menshov's theorem by replacing the whole spectrum $\mathbb{Z}$ by $\mathbb{Z}^+$.

Finally, we prove that relatively “small” parts of $\mathbb{Z}^+$ are already sufficient for representation in measure. In particular we construct “almost Hadamarian” and “almost squares” Menshov spectra in measure.

Theorems 1 and 2 are proved below in section 3. Theorem 3 (in a stronger form) is proved in section 4, and the last mentioned results in section 5.

The main results of this paper were stated without proofs in our note [18].

2. PRELIMINARIES

2.1. Notations. We denote by $\mathbb{T}$ the circle group, $\mathbb{T} = \mathbb{R}/2\pi\mathbb{Z}$, and we identify it in the standard way with the segment $[-\pi, \pi]$.

$\mathbf{m}$ is the normalized Lebesgue measure on $\mathbb{T}$.

$\mathbb{Z}^+$ or $\mathbb{N}$ is the set $\{1, 2, \dots\}$.

C is used to denote absolute positive constants, possibly different.

For a set $A \subset \mathbb{T}$ we define by $\mathbf{1}_A$ the function

$$\mathbf{1}_A(t) = \begin{cases} 1 & t \in A \\ 0 & t \notin A \end{cases}$$

The L_0 “norm” of any measurable function f from $\mathbb{T}$ to $\mathbb{C}$ is defined to be

$$\|f\|_0 := \inf \{ \epsilon : \mathbf{m}\{t : |f(t)| > \epsilon\} < \epsilon \} \quad . \quad (6)$$

This norm is sub-additive but not homogeneous. $L_0(\mathbb{T})$ is the space of all measurable functions on the segment $\mathbb{T}$ endowed with the norm $\|\cdot\|_0$ and is a topological linear space. Convergence in $\|\cdot\|_0$ is equivalent to convergence in measure.

For $f \in L^1(\mathbb{T})$ we denote by $\hat{f}(n)$ the Fourier coefficients of f and write

$$f(t) \sim \sum \hat{f}(k) e^{ikt} \quad .$$

The spectrum of f (denoted by $\text{spec } f$) is the support of $\hat{f}$, i.e. the set of integers where $\hat{f}$ is non zero.

The triangle function of width 2ϵ , denoted by τ_ϵ is defined on $[-\pi, \pi]$ by

$$\tau_\epsilon = \begin{cases} 1 - \frac{|x|}{\epsilon} & |x| < \epsilon \\ 0 & \text{otherwise} \end{cases} \quad . \quad (7)$$

It is well known (and easy to calculate) that $\hat{\tau}_\epsilon(n) > 0$ for any $n \in \mathbb{Z}$ and therefore

$$\|\hat{\tau}_\epsilon\|_1 = 1 \quad (8)$$

(as usual, $\|\cdot\|_p$, $1 \leq p \leq \infty$, for a function or a sequence denotes the $L^p(\mathbb{T})$ or l_p norms respectively). A trigonometric polynomial is a finite sum

$$P(t) = \sum c_k e^{ikt}$$

the degree of P , denoted by $\deg P$ is $\max\{|k| : k \in \text{spec } P\}$. We say about two trigonometric polynomials that the spectrum of P follows the spectrum of Q (or simply that P follows Q) if

$$l \in \text{spec } Q, k \in \text{spec } P \Rightarrow |l| < |k| \quad .$$

For a trigonometric polynomial $P = \sum c_k e^{ikt}$ we denote the partial sums by

$$S_n(P; t) := \sum_{k=-n}^n c_k e^{ikt} \quad .$$

and their maximum by

$$S^*(P; t) := \sup_{n \geq 0} |S_n(P; t)| \quad ,$$

Occasionally, we shall also need estimates of non-symmetric partial sums, so define

$$S_{n,m}(P; t) := \sum_{k=m}^n c_k e^{ikt}$$

$$S^{**} := \sup_{n,m \in \mathbb{Z}} |S_{n,m}| \quad .$$

Finally, we shall often use the following obvious, and somewhat rough estimates:

$$\|S^*(P)\|_\infty, \|S^{**}(P)\|_\infty \leq \|\widehat{P}\|_1$$

2.2. Special Products. Given $f : \mathbb{T} \rightarrow \mathbb{C}$ and $r \in \mathbb{N}$ we denote by $f_{[r]}$ the “contracted” function

$$f_{[r]}(t) = f(rt) \quad t \in \mathbb{T}.$$

We shall systematically use through this paper a “special product” of the form

$$H = Q_{[r]} \cdot P \quad . \tag{9}$$

where P and Q are trigonometric polynomials, $r > 2 \deg P$ and $\widehat{Q}(0) = 0$. The spectrum of H has a block structure, with each block containing a translated copy of $\text{spec } P$. So, if $n > 0$:

$$n = sr + l, \quad -\frac{1}{2}r \leq l < \frac{1}{2}r$$

we have:

$$\sum_{j=0}^n \widehat{H}(j) e^{ijt} = P(t) \cdot \sum_{k=1}^{s-1} \widehat{Q}(k) e^{ikrt} + \widehat{Q}(s) e^{isrt} \cdot \sum_{j=-\deg P}^l \widehat{P}(j) e^{ijt} \quad . \tag{10}$$

If $n < 0$ an analogous equality holds for $\sum_{j=n}^0$.

The second sum on the right hand side we usually bound by $\|\widehat{Q}\|_\infty \cdot \|\widehat{P}\|_1$.

Sometimes, as in the proof of lemma 2.1 below, we use the trivial estimate for H :

$$\|S^{**}(H)\|_\infty \leq \|\widehat{P}\|_1 \cdot \|\widehat{Q}\|_1 \tag{11}$$

2.3. Separation of spectra. Our starting point is a fundamental principle, used by Menshov in his “correction” and “representation” theorems. In a few words, it goes as follows: given f we decompose it into “elementary pieces” and then by correcting in a small measure we can localize the Fourier transform of each piece in a “personal” part of the spectrum in such a way that the supports of different pieces are essentially disjoint. It allows to avoid “unpleasant” resonance with the Dirichlet kernel and control the size of the Fourier partial sums. Menshov did it using a delicate and difficult technique based on his so-called “Dirichlet factor lemma” (see [6], chap. V). A new version of Menshov’s approach (using the special products above) was outlined in [12], sect. 1, in the framework of the correction theorem. A similar technique for representation results was developed by Körner, see [16].

The following lemma may serve as a good illustration of the modern version of Menshov's approach:

Lemma 2.1. *Given any $\epsilon > 0$, $\delta > 0$, there exists a trigonometric polynomial Q such that*

- (i) $\widehat{Q}(0) = 0$, $\|\widehat{Q}\|_\infty < \delta$;
- (ii) $\mathbf{m}\{t : |Q(t) - 1| > \delta\} < \epsilon$;
- (iii) $\|S^{**}(Q)\|_\infty < C\epsilon^{-1}$.

Such a statement, with a little weaker form of (iii) can be found in [16], lemma 1; but we need the present form, especially for the proof of theorem 2. The proof below follows essentially [12], sect. 1.

Proof. Fix a large integer K . Let $f := \tau_{2\pi/K}$, $g := 1 - \frac{4}{\epsilon}\tau_{\epsilon/4}$. Approximating them by Fourier partial sums we get polynomials F and G satisfying

$$\|\widehat{F - f}\|_1 < c, \quad \|\widehat{G - g}\|_1 < c, \quad \widehat{G}(0) = 0$$

where c is small. Let T be the translation by $\frac{2\pi}{K}$. Set

$$\begin{aligned} Q_s &:= T^s(F) \cdot G_{[N_s]}; \\ Q &:= \sum_{s=1}^K Q_s, \end{aligned} \tag{12}$$

where $N(1) > 2 \deg F$ and $N(s)$ grow sufficiently fast to ensure the separation of spectra. It follows:

$$\|\widehat{Q}\|_\infty = \max_s \|\widehat{Q_s}\|_\infty = \|\widehat{F}\|_\infty \|\widehat{G}\|_1 < \frac{2}{K} \cdot \frac{4}{\epsilon}.$$

So, if $K(\epsilon, \delta)$ is sufficiently large we get (i). Obviously

$$\sum_{s=1}^K T^s(f) \cdot g_{[N(s)]} = 1$$

outside a set of measure $< \epsilon$, so if c is sufficiently small we get (ii). Now denote:

$$\widetilde{G}(t) = \sum_{k>0} \widehat{G}(k) e^{ikt}$$

The separation of spectra implies a decomposition

$$\Sigma^{(n)} := \sum_{k=0}^n \widehat{Q}(k) e^{ikt} = \Sigma_1 + \Sigma_2$$

where Σ_1 contains all polynomials of the form $T^s(F) \widetilde{G}_{[N(s)]}$ with spectra belonging to $[0, n]$ and the reminder Σ_2 is a segment of a polynomial of the same form. According to section 2.2 we have

$$\begin{aligned} \|\Sigma_2\|_\infty &\leq \|\widehat{F}\|_1 \cdot \|\widehat{G}\|_1 \\ \|\Sigma_1\|_\infty &\leq \left\| \sum |T^s(F)| \right\|_\infty \cdot \|\widehat{G}\|_1, \end{aligned}$$

so $c < \frac{1}{K}$ implies $\|\Sigma^{(n)}\|_\infty < C\epsilon^{-1}$. The same is true for $n < 0$ and we get (iii). $\square$

2.4. Analytic polynomials. An analytic polynomial is a trigonometric polynomial P with positive spectrum, i.e.

$$P(t) = \sum_{n \geq 0} c_n e^{int} \quad .$$

Sections 4 and 5 will contain most of the discussion about these objects. For the time being, we wish to remind the reader the generally known fact that analytic polynomials are dense in L^0 . We formulate it in an equivalent way:

Lemma 2.2. *For every $\epsilon > 0$ there exists an analytical polynomial R_ϵ such that*

$$\|R_\epsilon - 1\|_0 < \epsilon \quad (13)$$

Proof. Let $g(e^{it})$ be a real (smooth) function with zero average and $< -1/\epsilon$ for $|t| > \epsilon/3$. Denote by G the Poisson integral of g ; by $\tilde{G}$ the conjugate harmonic function and write

$$F = \exp(G + i\tilde{G})$$

Clearly, $F(0) = 1$ and $\|F(e^{it})\|_0 < \epsilon$ so taking R_ϵ to be a Taylor approximation of $1 - F$ we get the result. $\square$

3. LACUNARY SPECTRA

This section is devoted to the proof of theorems 1 and 2.

3.1. The blocks $B(s, a)$. Our starting point to these two theorems, as well as to the theorems of section 5, are blocks $B(s, a) \subset \mathbb{Z}$, defined for $s, a \in \mathbb{N}$ as follows:

$$\begin{aligned} B_1(s, a) &:= \{-sa, -(s-1)a, \dots, -a, a, 2a, \dots, sa\} \\ B_1^+(s, a) &:= B_1(s, a) \cap \mathbb{Z}^+ \\ B_2(s, a) &:= \bigcup_{|k| \leq s} k + B_1^+(s, (2s)^{k+s}a) \\ B(s, a) &:= B_1(s, (2s)^{2s+2}a) + (B_2(s, a) \cup -B_2(s, a)) \end{aligned} \quad (14)$$

where we understand $x + B$ and $A + B$ in the standard sense:

$$\begin{aligned} x + A &:= \{x + a : a \in A\} \\ A + B &:= \{a + b : a \in A, b \in B\} \quad . \end{aligned}$$

The following can be checked directly from the definition:

Proposition 3.1. *For any $b \in B(s, a)$ there exists $l = l(b)$, $0 < |l| < C(s)$ such that $|b - la| < C(s)$. Further, $b_1 \neq b_2 \Rightarrow l(b_1) \neq l(b_2)$.*

This means that $B(s, a)$ is a subset of a “small” perturbation of a linear progression (if $a \gg s$). In particular, $B(s, a)$ is quite sparse: for $b_1 \neq b_2$ in $B(s, a)$

$$|b_1 - b_2| > a - 2C(s) \quad . \quad (15)$$

Another point to notice is that $B(s, a)$ has a rather large “hole” near zero. We might quantify this as

$$\text{dist}(B, 0) > (2s)^{2s+1}a \quad . \quad (16)$$

$B(s, a)$ is clearly symmetric with respect to zero. Actually, the component $-B_2(s, a)$ is here only to assure that. For the proof of lemma 3.2 below, it would have been enough to define $B(s, a)$ as $B_1(s, (2s)^{2s+2}a) + B_2(s, a)$

3.2. Approximation with spectrum in $B(s, a)$.

Lemma 3.2. *For every $\epsilon > 0$, $\delta > 0$ and $f \in L^0$ there exists an $S = S(f, \epsilon, \delta)$ with the following property. Given $s > S$ and $a \in \mathbb{N}$ one may construct a trigonometric polynomial P satisfying*

- (i) $\mathbf{m} \{t : |P - f| > \delta\} < \epsilon$;
- (ii) $\text{spec } P \subset B(s, a)$;
- (iii) $\mathbf{m} \{t : S^{**}(P; t) > C\epsilon^{-1}(|f(t)| + \delta)\} < \epsilon$.

Proof. We shall perform this approximation in three steps.

Step 1: Approximate f by a polynomial P_1 satisfying

$$\mathbf{m} \{t : |f - P_1| > \delta_1\} < \epsilon_1 \quad (17)$$

where

$$\delta_1 := \frac{1}{3}\delta, \quad \epsilon_1 := \frac{1}{3}\epsilon.$$

Step 2: Define

$$\epsilon_2 := \frac{\epsilon}{6 \deg P_1 + 3}, \quad \delta_2 := \frac{\delta}{3\|\widehat{P_1}\|_1} \quad (18)$$

And use lemma 2.2 to get an analytic polynomial Q_2 satisfying

$$\mathbf{m} \{t : |Q_2 - 1| > \delta_2\} < \epsilon_2 \quad (19)$$

Step 3: Use lemma 2.1 with

$$\epsilon_3 := \frac{1}{3}\epsilon, \quad \delta_3 := \frac{\delta}{6\|\widehat{P_1}\|_1\|\widehat{Q_2}\|_1} \quad (20)$$

to get Q_3 satisfying

$$\widehat{Q_3}(0) = 0; \quad (21)$$

$$\|\widehat{Q_3}\|_\infty \leq \delta_3; \quad (22)$$

$$\|S^{**}(Q_3)\|_\infty \leq C\epsilon_3^{-1}; \quad (23)$$

$$\mathbf{m} \{t : |Q_3 - 1| > \delta_3\} < \epsilon_3.$$

We have now gathered all the data we need to define S :

$$S(f, \epsilon, \delta) := \max \{\deg P_1, \deg Q_2, \deg Q_3\}. \quad (24)$$

Let us now show how we can construct P supported on $B(s, a)$. Fix some $s > S$ and any integer a . Clearly (remember that Q_2 is analytic)

$$\text{spec } (Q_2)_{[a]} \subset B_1^+(s, a)$$

or

$$\text{spec } (e^{ikt} \cdot (Q_2)_{[a]}) \subset k + B_1^+(s, a). \quad (25)$$

So define

$$P_2 := \sum_{|k| \leq \deg P_1} \widehat{P_1}(k) e^{ikt} \cdot (Q_2)_{[p(k)]} \quad (26)$$

$$p(k) := a(2s)^{k+s} \quad (27)$$

On one hand, (25) and (14) imply: $\text{spec } P_2 \subset B_2(s, a)$. On the other hand,

$$|P_2 - P_1| = \left| \sum \widehat{P_1}(k) e^{ikt} (1 - (Q_2)_{[p(k)]}) \right|$$

so (18) and (19) gives

$$\begin{aligned} \mathbf{m} \left\{ t : |P_2 - P_1| > \frac{1}{3}\delta \right\} &\leq \\ &\leq \sum_{|k| \leq \deg P_1} \mathbf{m} \left\{ t : \left| \widehat{P_1}(k)(1 - (Q_2)_{[p(k)]}) \right| > |\widehat{P_1}(k)|\delta_2 \right\} \\ &< (2 \deg P_1 + 1)\epsilon_2 = \frac{1}{3}\epsilon \end{aligned} \quad (28)$$

and thus

$$\mathbf{m} \left\{ t : |P_2 - f| > \frac{2}{3}\delta \right\} < \frac{2}{3}\epsilon \quad . \quad (29)$$

Finally, define

$$P \equiv P_3 = (Q_3)_{[p(s+2)]} P_2 \quad .$$

From (21) we get that $\text{spec}(Q_3)_{[p(s+2)]} \subset B_1(s, p(s+2))$, which implies (ii). First, an estimate of $P - P_2$. Obviously

$$\mathbf{m} \left\{ x : |P - P_2| > \frac{1}{3}\delta \right\} \leq \mathbf{m} \left\{ t : |1 - Q_3| > \frac{\delta}{3\|P_2\|_\infty} \right\} \quad .$$

The definition of P_2 , (26), gives the estimate

$$\|P_2\|_\infty \leq \|\widehat{P_1}\|_1 \|\widehat{Q_2}\|_1$$

so, using (20),

$$\mathbf{m} \left\{ t : |P - P_2| > \frac{1}{3}\delta \right\} \leq \mathbf{m} \left\{ t : |1 - Q_3| > \delta_3 \right\} < \frac{1}{3}\epsilon \quad . \quad (30)$$

Summing (29) and (30) gives

$$\mathbf{m} \left\{ t : |f - P| > \delta \right\} < \epsilon \quad .$$

To estimate $S^{**}(P)$ note that, using (27), (26) and (24),

$$p(s+2) = (2s)^{2s+2}a > 2 \deg P_2, \quad (31)$$

so we may use (10) and get

$$S^{**}(P; t) \leq \|S^{**}(Q_3)\|_\infty |P_2(t)| + 2\|\widehat{Q_3}\|_\infty \|\widehat{P_2}\|_1 \quad .$$

As before, estimate $\|\widehat{P_2}\|_1$ directly from (26) and get

$$\|\widehat{P_2}\|_1 \leq \|\widehat{P_1}\|_1 \|\widehat{Q_2}\|_1$$

which, together with (23), (22) and (20) gives

$$S^{**}(P; t) \leq C\epsilon^{-1}|P_2(t)| + \frac{1}{3}\delta \quad .$$

and remembering (29), the lemma is proved. $\square$

3.3. Almost Hadamarian lacunarity. The proof of theorem 1 contains two components: showing that every set Λ containing $B(s, a)$ for arbitrarily large s is a Menshov spectrum and that such a set conforming to the requirements of the theorem can be build. Let us start with the first component.

Lemma 3.3. *If $\Lambda \subset \mathbb{Z}$ satisfies $B(s_k, a_k) \subset \Lambda$ for a sequence $s_k \rightarrow \infty$ then it is a Menshov spectrum.*

Proof. Let f be in L^0 . We shall construct by induction a sequence of polynomials P_n satisfying

- (i) $\mathbf{m} \left\{ x : |f - \sum_{k=1}^n P_k| > 2^{-2n} \right\} < 2^{-n}$;
- (ii) $\text{spec } P_n \subset \Lambda$;
- (iii) P_n follows P_{n-1} ;

$$(iv) \quad \|S^*(P_n)\|_0 \leq C2^{-n}.$$

This finishes the proof as it is clear that $\sum_{n=1}^{\infty} P_n$ yields a trigonometric series converging to f almost everywhere.

Assume $P_0, \dots, P_{n-1}$ has been constructed. Define

$$F_n := f - \sum_{k=1}^{n-1} P_k$$

$$\epsilon_n := 2^{-n}$$

$$\delta_n := 2^{-2n} \quad .$$

Lemma 3.2 gives $S = S(F_n, \epsilon_n, \delta_n)$ and we may pick some $s > \max\{S, \deg P_{n-1}\}$ and some a for which $B(s, a) \subset \Lambda$. Thus there exist P_n satisfying the requirements of lemma 3.2, namely

$$\mathbf{m}\{t : |P_n - F_n| > \delta_n\} < \epsilon_n \quad (32)$$

$$\mathbf{m}\{t : S^*(P_n; t) > C\epsilon_n^{-1}(|F_n(t)| + \delta_n)\} < \epsilon_n \quad (33)$$

$$\text{spec } P \subset B(s, a) \subset \Lambda \quad .$$

Now, $s > \deg P_{n-1}$ implies requirement (iii) of the lemma (remember (16)). Requirement (i) is an immediate consequence of (32) since

$$f - \sum_{k=1}^n P_k = F_n - P_n$$

requirement (iv) of the lemma is a combination of (33) and our induction assumption (requirement (i)) for P_{n-1} :

$$\mathbf{m}\{x : |F_n| > 2^{-2n+2}\} < 2^{-n+1}$$

and the lemma is proved. $\square$

To finish the proof of theorem 1 it is enough to find a symmetric set Λ conforming to (3) and containing a sequence of $B(s_k, a_k)$. It can be done by a simple induction. We may assume that $\{\epsilon_n\}$ is monotone. At each step we either add to Λ an entire block B or define two (symmetric) members of Λ . More precisely, let

$$\{\lambda(j)\}_{|j| \leq m}$$

be already defined.

(a) If there exists an s such that

$$\epsilon(m) < \frac{1}{2C(s)} \quad , \quad (34)$$

where $C(s)$ is the constant from proposition 3.1, we take the maximal s satisfying this inequality and include all elements of the block $B(s, a)$ as new members of Λ . a here is chosen sufficiently large to ensure (3) for $n = m$ and simultaneously

$$\frac{a - 2C(s)}{aC(s)} > \frac{1}{2C(s)}$$

which implies (3) for all

$$m < n < m + \frac{1}{2}|B(s, a)|$$

due to $\max B(s, a) < C(s)a$ and (15).

(b) If such an s does not exist, we just define

$$\lambda(m+1) > \lambda(m)(1 + \epsilon(m)) \quad .$$

Obviously, the condition (34) will be fulfilled infinitely many times, and the corresponding values of s will tend to infinity; this finishes the proof. $\square$

As discussed in the introduction, this result is sharp.

3.4. Squares. Lemma 3.3 allows one to get a Menshov spectrum satisfying

$$\lambda(n) = \pm n^2 + O(n) \quad .$$

To obtain such a result with *arbitrarily slow* growing perturbation (that is, to prove theorem 2) we need a more delicate approach. Essentially, we cannot use approximate arithmetic progressions which start from zero (as $B(s, a)$ does) and the method above fails. However, translated $B(s, a)$'s do exist in the neighborhood of the squares, which, as will be shown below, is enough.

We start with an elementary estimate of Riesz products. It is interesting to compare this to the corresponding estimate in section 5, which requires more probabilistically oriented techniques.

Lemma 3.4. *There exists a sequence L_k such that for every $\nu = \{\nu_k\} \subset \mathbb{Z}$ satisfying*

$$\frac{\nu_k}{\nu_{k-1}} > L_k$$

we have for almost all $t \in \mathbb{T}$

$$3^{-n} < \prod_{k=1}^n (1 - \cos \nu_k t) < c^n \quad \forall n > N(\nu; t)$$

where $c < 1$ is an absolute constant.

Proof. Taking log the problem turns into proving that

$$-nC_1 < \sum_{k=1}^n \log(1 - \cos \nu_k t) < -nC_2$$

Denote

$$\begin{aligned} A &:= \int_{\mathbb{T}} \log(1 - \cos t) dm(t) \\ F &:= \log(1 - \cos t) - A \\ F_k &:= F_{[\nu_k]} \quad . \end{aligned}$$

One can check that for $\{L_k\}$ growing sufficiently fast,

$$\left| \int F_k F_{k'} \right| < 2^{-(k+k')} \quad \forall k \neq k'. \quad (35)$$

Thus in this case, the F_k 's are almost orthogonal in a sense. We will use the classic “law of large numbers” for orthonormal sequences (see, for example, [1], theorem 5.3.5): if $\{\varphi_k\}$ is an orthonormal system then

$$\sum_{k=1}^n \varphi_k(t) = o(n) \quad \text{a.e.}$$

The result is true also for our case. Indeed, (35) implies the estimate

$$\left\| \sum c_k F_k \right\|_2 \leq C \sqrt{\sum c_k^2} \quad \forall \{c_k\}$$

which in turn ensures, using Schur's theorem (see [1], theorem 3.2.2) that the system F_k can be extended to an orthogonal equinormed system on a longer interval. Therefore

$$\sum_{k=1}^n \log(1 - \cos \nu_k t) = nA + o(n)$$

almost everywhere. The actual value of A can be calculated using the average property for harmonic functions once it is noted that $1 - \cos t = \frac{1}{2}|1 - e^{it}|^2$ and the result is

$$A = -\log 2$$

which proves the lemma. $\square$

We may now continue with the proof of theorem 2. For $s, a, \nu \in \mathbb{N}$, $\nu > \max B(s, a)$, define

$$B(s, a, \nu) = (-\nu + B(s, a)) \cup (\nu + B(s, a)) \quad . \quad (36)$$

Note that $B(s, a, \nu)$ is symmetric, because $B(s, a)$ is.

Lemma 3.5. *If $\Lambda \subset \mathbb{Z}$ satisfies that for some sequences $s_k \rightarrow \infty, a_k, \nu_k \rightarrow \infty$*

$$\begin{aligned} B_k := B(s_k, a_k, \nu_k) &\subset \Lambda \\ \text{dist}(B_k, 0) &\rightarrow \infty \end{aligned}$$

then it is a Menshov spectrum.

Proof. Let $f \in L^0$ be any function. As before, we shall construct by induction a series of polynomials such that the sum $\sum P_n$ will converge to f . Assume $P_1, \dots, P_{n-1}$ have been constructed. Define

$$F_n = f - \sum_{k=1}^{n-1} P_k \quad . \quad (37)$$

We write $\epsilon_n := n^{-2}$, $\delta_n := 4^{-n}$ and define $S_n = S(F_n, n^{-2}, 4^{-n})$ to be the constant defined in lemma 3.2. Find some $s_n > S_n$, a_n and

$$\nu_n > \nu_{n-1} L_n \quad (38)$$

(L_n from lemma 3.4) such that

$$\text{dist}(B(s_n, a_n, \nu_n), 0) > \deg P_{n-1}$$

$$B(s_n, a_n, \nu_n) \subset \Lambda \quad (39)$$

and let P_n^1 be the polynomial given by lemma 3.2 for the same ϵ_n , δ_n and F_n , and for s_n and a_n . Finally, we define

$$P_n(t) := \cos \nu_n t \cdot P_n^1(t) \quad . \quad (40)$$

So, the above process is an inductive definition of sequences F_n , s_n , a_n , ν_n , P_n^1 and P_n satisfying (37), (38), (39), (40) and so on. Let us now draw conclusions from these. First,

$$\begin{aligned} \text{spec } P_n &\subset B(s_n, a_n, \nu_n) \\ \mathbf{m} \{t : |F_n(t) \cos \nu_n t - P_n(t)| > 4^{-n}\} &< n^{-2} \end{aligned} \quad (41)$$

and (41) can be rephrased as

$$\mathbf{m} \{x : |F_{n+1}(t) - F_n(t)(1 - \cos \nu_n t)| > 4^{-n}\} < n^{-2}.$$

So we may conclude that

$$|F_{n+1}(t) - F_n(t)(1 - \cos \nu_n t)| \leq 4^{-n} \quad \forall n > N_1(t).$$

Here, and in what follows, we denote by $N_j(t)$ integer valued, measurable, almost everywhere defined functions. Since $\nu_n > L_n \nu_{n-1}$, lemma 3.4 implies that for almost all t ,

$$3^{-n} < \prod_{k=1}^n |1 - \cos \nu_k t| < c^n \quad \forall n > N_2(t) \quad (42)$$

(assume that $N_2 > N_1$). This implies a rough estimate of partial products

$$\prod_{k=m+1}^n |1 - \cos \nu_k t| < \frac{c^n}{3^{-m}} \quad \forall n > m > N_2(t)$$

which is enough to do away with the 4^{-n} errors: if $n > m > N_2(t)$ then

$$\begin{aligned} \left| F_{n+1}(t) - F_m(t) \prod_{k=m}^n (1 - \cos \nu_k t) \right| &\leq \sum_{k=m}^n 4^{-k} \prod_{l=k+1}^n |1 - \cos \nu_l t| \\ &< \sum 4^{-k} \frac{c^n}{3^{-k}} < 4c^n \end{aligned} \quad (43)$$

And therefore (using (42))

$$|F_n(t)| < c_1^n \quad c_1 < 1 \quad \forall n > N_3(t) \quad (44)$$

This shows that

$$\sum_{k=0}^n P_k \rightarrow f$$

so we are only left with the estimates of $S^*(P_n)$. A little consideration shows

$$S^*(P_n; t) \leq S^{**}(P_n^1; t)$$

and condition (iii) of lemma 3.2 gives

$$\mathbf{m} \{t : S^{**}(P_n^1; t) > Cn^2(|F_n(t)| + 4^{-n})\} \leq Cn^{-2}$$

so due to (44),

$$S^*(P_n; t) < Cn^2 c_1^n \quad \forall n > N_4(t)$$

and the lemma is proved. $\square$

To deduce theorem 2 consider now $B = B(s, 2a, a^2)$. For sufficiently large a we will have, using proposition 3.1:

$$b \in B \cap \mathbb{Z}^+ \Rightarrow b = k^2 + \tau(b), \quad k = a + l(b)$$

with

$$|\tau(b)| < C(s) < \sqrt{\omega(k)}$$

Lemma 3.5 implies that the set

$$\bigcup_{s \geq 1} B(s, 2a(s), a^2(s))$$

is a Menshov spectrum, and the result follows. $\square$

Remark. Another direct consequence of lemma 3.5: any symmetric Λ containing arbitrary long segments of integers is a Menshov spectrum; first proved, using a different technique, in [13].

3.5. Theorem 2 too is sharp, in the following sense:

Proposition 3.6. *Any sequence*

$$\Lambda(n) = \text{sign}(n) \cdot n^2 + O(1)$$

is not a Menshov spectrum.

The proof will follow from the next two propositions:

Proposition 3.7. *If Λ is a Menshov spectrum, $m \in \mathbb{N}$ and $n \in \mathbb{N}$ then*

- (i) $\Lambda - n$ *is a Menshov spectrum*
- (ii) $(\frac{1}{m}\Lambda) \cap \mathbb{Z}$ *is a Menshov spectrum*

Proof. Start with (i). Let $f \in L^0$. Define

$$g(t) = e^{int} f(t)$$

and use the fact that Λ is a Menshov spectrum to write

$$\sum_{k \in \Lambda} c_k e^{ikt} = g(t) \quad .$$

Clearly, this implies that $c_k \rightarrow 0$ when $|k| \rightarrow \infty$ and therefore we may shift the sum in a finite number of places:

$$\lim_{N \rightarrow \infty} \sum_{\substack{k \in \Lambda \\ |k| < N}} c_k e^{ikt} = \lim_{N \rightarrow \infty} \sum_{\substack{k \in \Lambda \\ |k-n| < N}} c_k e^{ikt} = e^{int} \cdot \lim_{N \rightarrow \infty} \sum_{\substack{l \in \Lambda-n \\ |l| < N}} c_{l+n} e^{ilt}$$

and thus part (i) is completed. For part (ii), define

$$g = f_{[m]}$$

and let c_k be numbers such that

$$\sum_{k \in \Lambda} c_k e^{ikt} = g(t)$$

for a.e. t . Then for a.e. $t \in [0, \frac{1}{m})$,

$$\sum_{r=0}^m g(t + r/m) = \sum_{k \in \Lambda} c_k e^{ikt} \sum_r e^{ikr/m} = \sum_{\substack{k \in \Lambda \\ k \equiv 0 \pmod{m}}} m c_k e^{ikt}$$

which gives

$$f(t) = \frac{1}{m} \sum g\left(\frac{t+r}{m}\right) = \sum_{k \in \Lambda \cap m\mathbb{Z}} c_k e^{ikt/m}$$

and so defining $d_k = c_{mk}$ we get

$$\sum_{k \in (\frac{1}{m}\Lambda) \cap \mathbb{Z}} d_k e^{ikt} = f(t)$$

for almost every $t \in \mathbb{T}$. □

In light of this, to prove proposition 3.6, it is enough to show that quadratic residues admit arbitrarily large holes in $\mathbb{Z}_p$. More precisely, we use the following well known fact:

Proposition 3.8. *For any $r \geq 2$ there exists a p_0 such that for any prime $p > p_0$ there exists an integer $0 \leq x < p$ satisfying*

$$\left(\frac{x+i}{p}\right) = -1 \quad \forall 1 \leq i \leq r$$

and $\left(\frac{a}{p}\right)$ is the Legendre symbol.

This is a corollary of theorem 1.4.2.1 from [11]. The author attributes this theorem to Davenport and A. Weil.

Proof of proposition 3.6: Let Λ satisfy

$$|\Lambda(n) - \text{sign } n \cdot n^2| < A \quad .$$

Use proposition 3.8 with $r = 2A$ to get a corresponding p_0 ; pick some $p > p_0$ for which $\left(\frac{-1}{p}\right) = 1$ (quadratic reciprocity says that this is equivalent to $p \equiv 1 \pmod{4}$) and we shall get an interval $(m - A, m + A)$ in $\mathbb{Z}_p$ which does not contain any $\pm n^2 \pmod{p}$. Thus

$$\Lambda \cap (m + p\mathbb{Z}) = \emptyset$$

and according to proposition 3.7, Λ is not a Menshov spectrum. $\square$

4. POSITIVE SPECTRA: REPRESENTATION IN MEASURE

4.1. We have seen in the introduction that $\mathbb{Z}^+$ is not a Menshov spectrum. However, replacing convergence almost everywhere by convergence in measure enables us to get an “analytic” representation theorem. This result (theorem 3) is proved below. Actually, we prove it in a stronger form, inspired by Talalyan’s paper [15] where the following definition was introduced:

Definition 2. A series $\sum f_j$ converges to f asymptotically in $L^p(\mathbb{T})$ if for any $\epsilon > 0$ there exists a compact $K(\epsilon)$ in $\mathbb{T}$, with $\mathbf{m}(\mathbb{T} \setminus K) < \epsilon$, and $\sum f_j = f$ in $L^p(K)$.

Clearly asymptotic convergence in L^p for some $p \in [1, \infty]$ implies convergence in measure, while asymptotic convergence in L^∞ is equivalent to convergence a.e.

We can now formulate our result.

Theorem 4. *Given $f \in L^0(\mathbb{T})$ one can define coefficients $\{c_k\}_{k=1}^\infty$ such that*

$$\sum_{k>0} c_k e^{ikt} = f(t)$$

asymptotically in $L^2(\mathbb{T})$.

4.2. **Analytic approximation.** The following lemma is the basis of this section. It gives an analytic approximation of 1 with the necessary control of the partial sums.

Lemma 4.1. *For every $\epsilon > 0$ there exists an analytical polynomial*

$$Q(t) = Q_\epsilon(t) = \sum_{k>0} c_{k,\epsilon} e^{ikt}$$

and a measurable set $E = E_\epsilon$ such that

- (i) $\|\widehat{Q}\|_\infty < \epsilon$;
- (ii) $\mathbf{m}(\mathbb{T} \setminus E) < \epsilon$;
- (iii) $|Q - 1| < \epsilon$ on E ;
- (iv) For every n , $\|S_n(Q)\|_{L^2(E)} < 2$;
- (v) For every n , $\mathbf{m}\{t : |S_n(Q; t)| > 2\} < \epsilon$.

Proof. As in lemma 2.1, we follow essentially the construction from [12]. Using lemma 2.2 fix an analytical polynomial G such that

$$\|G - 1\|_0 < \frac{1}{4}\epsilon \quad (45)$$

and an integer K

$$K > \left(\frac{2}{\epsilon} \|\widehat{G}\|_1\right)^2 \quad (46)$$

Let f be the triangle function $\tau_{2\pi/K}$ and approximate it by a Fourier partial sum F such that

$$\|\widehat{F - f}\|_1 < \frac{\epsilon}{10K\|\widehat{G}\|_1} \quad (47)$$

As before, let T be the translation by $2\pi/K$,

$$T(f)(t) := f(t + 2\pi K^{-1}),$$

Set

$$N_s := K(2 \deg F + \deg G + 2)^s \quad (48)$$

and finally, define

$$\begin{aligned} Q &:= \sum_{s=1}^K Q_s, \\ Q_s &:= T^s(F) \cdot G_{[N_s]} \quad . \end{aligned}$$

The choice of $\{N_s\}$ ensures that all Q_s are analytic and that their spectra follow one another. This implies, in particular, that

$$\|\widehat{Q}\|_\infty = \max \|\widehat{Q_s}\|_\infty \leq \max \|T^s F\|_\infty \max \|\widehat{G_{[N_s]}}\|_1 = \frac{1}{K} \|\widehat{G}\|_1 < \epsilon$$

so we get requirement (i).

Now set

$$\begin{aligned} I_s &:= \left[\frac{2\pi(s-1)}{K}, \frac{2\pi(s+1)}{K} \right], \quad 1 \leq s \leq K \\ U_s &:= \{t \in I_s : |G_{[N_s]}(t) - 1| < \epsilon/4\} \\ E &:= \mathbb{T} \setminus \bigcup U_s \end{aligned} \quad (49)$$

(45) and the fact that $K|N_s$ (48) imply that $\mathbf{m}U_s < \frac{1}{4}\epsilon \cdot \mathbf{m}I_s$, so

$$\mathbf{m}\mathbb{T} \setminus E < \frac{1}{4}\epsilon \quad . \quad (50)$$

To verify requirement (iii), set

$$Q' := \sum_{s=1}^K T^s(f) \cdot G_{[N_s]} \quad .$$

For any t , for at most two values of s the value of $T^s(f)$ is non zero, and their sum is 1. Meanwhile, if $t \in E$ then the factor $G_{[N_s]}$ belongs to $(1 - \frac{1}{4}\epsilon, 1 + \frac{1}{4}\epsilon)$ for both s 's as follows from (49). So

$$|Q'(t) - 1| < \frac{1}{2}\epsilon \quad \forall t \in E.$$

Passing from Q' to Q , (47) implies

$$\left\| (T^s(f - F) \cdot G_{[N_s]})^\wedge \right\|_1 \leq \| \widehat{f - F} \|_1 \| \widehat{G} \|_1 < \frac{\epsilon}{10K}$$

and the equality

$$Q = Q' + \sum (T^s f - T^s F) \cdot G_{[N_s]}$$

gives requirement (iii). For requirements (iv) and (v), fix n . Because the spectra of the Q_s follow each other there exists a j such that

$$S_n(Q) = \sum_{s < j} Q_s + S_n(Q_j)$$

The sum on the right hand side can be estimated on E exactly as before and we get

$$\left| \sum_{s < j} Q_s(t) \right| < 1 + \frac{3}{4}\epsilon \quad \forall t \in E. \quad (51)$$

Whereas

$$\begin{aligned} \|S_n(Q_j)\|_{L^2(\mathbb{T})} &\leq \|Q_j\|_2 < \|T^j(F)\|_2 \|G_{[N_j]}\|_\infty < \|f\|_2 \|\widehat{G}\|_1 \\ &< K^{-1/2} \cdot \|\widehat{G}\|_1 < \epsilon \end{aligned} \quad (52)$$

and (considering ϵ to be sufficiently small) we get (iv). (52) also gives (v), because we have

$$\mathbf{m} \left\{ t : |S_n(Q_j)| > \frac{1}{2} \right\} < 4\epsilon^2$$

which, together with (51) and (50) finishes the lemma. $\square$

4.3. Proof of theorem 4. We shall construct by induction analytic polynomials P_n and sets E_n such that

- (i) $\mathbf{m}(\mathbb{T} \setminus E_n) < 2^{-n}$;
- (ii) $|\sum_{k=1}^n P_k - f| < 2^{-n}$ on E_n ;
- (iii) P_n follows P_{n-1} ;
- (iv) for any k , $\|S_k(P_n)\|_{L^2(E_n \cap E_{n-1})} < C2^{-n}$.

Having these we get the theorem. Indeed, requirement (iii) allows us to define a sequence $\{c_k\}_{k=1}^\infty$ such that

$$P_n = \sum_{k=\deg P_{n-1}+1}^{\deg P_n} c_k e^{ikt}.$$

Requirements (ii) and (iv) show in a standard way that the series $\sum c_k e^{ikt}$ converges to f in $L^2(\bigcap_{n=N}^\infty E_n)$ for any N , and combining this with requirement (i) we get the theorem.

Let us now assume $P_1, \dots, P_{n-1}$ have been constructed, and show how to build P_n . Define

$$F_n := f - \sum_{k=1}^{n-1} P_k \quad (53)$$

First approximate F_n by a trigonometric polynomial G_n such that

$$|G_n - F_n| < 2^{-(n+1)} \quad \text{on } D_n, \quad \mathbf{m}(\mathbb{T} \setminus D_n) < 2^{-(n+1)}. \quad (54)$$

Put

$$\epsilon(n) := \frac{2^{-(n+1)}}{\|\widehat{G_n}\|_1 + 1} \quad (55)$$

and using lemma 4.1 for $\epsilon(n)$ we get $Q = Q_{\epsilon(n)}$. Set

$$P_n := Q_{[r_n]} G_n \quad (56)$$

where

$$r_n := \deg P_{n-1} + 2 \deg G_n + 1.$$

This choice of r_n will ensure that P_n are analytic, and that (iii) is fulfilled. Define E_n to be

$$E_n := (E_{\epsilon(n)})_{[r_n]} \cap D_n \quad (57)$$

where $E_{\epsilon(n)}$ comes from lemma 4.1 and $E_{[r]}$ is defined by the equality $(\mathbf{1}_E)_{[r]} \equiv \mathbf{1}_{(E_{[r]})}$. Clearly, $\mathbf{m}(E_{[r]}) = \mathbf{m}E$. So, condition (ii) of lemma 4.1 together with (54) gives requirement (i). Condition (iii) of lemma 4.1 says that for $t \in E_n$, $|Q_{[r_n]}(t) - 1| < \epsilon(n)$, so

$$|P_n - G_n| < 2^{-(n+1)} \quad \text{on } E_n \quad (58)$$

and summing (53), (54) and (58) we end up with requirement (ii) fulfilled.

Requirement (iv): Now we use (10) for the polynomial (56):

$$\begin{aligned} \sup_k \|S_k(P_n)\|_{L^2(E_n \cap E_{n-1})} &\leq \\ &\leq \|G_n\|_{L^\infty(E_n \cap E_{n-1})} \cdot \max_k \|S_k(Q_{[r_n]})\|_{L^2(E_n)} + \|\widehat{Q}\|_\infty \cdot \|\widehat{G}\|_1 \\ &< \|G_n\|_{L^\infty(D_n \cap E_{n-1})} \cdot \max \|S_k(Q)\|_{L^2(E_{\epsilon(n)})} + 2^{-n} \end{aligned}$$

(here (57), (55) and condition (i) of lemma 4.1 were used). The product on the right hand side is

$$< 2 \{ \|F_n\|_{L^\infty(E_{n-1})} + 2^{-n} \}$$

due to condition (iv) of lemma 4.1 and (54). Finally, we use for F_n assumption (ii) of the induction (in the $n-1$ 'th step) and get condition (iv). This finishes the proof of the theorem. $\square$

Remarks

1. In the theorem above one can replace asymptotic convergence in $L^2(\mathbb{T})$ by the same convergence in $L^p(\mathbb{T})$ ($p < \infty$). The appropriate version of lemma 4.1 can be proved identically, using the classical result the $\|S_n(F)\|_p < C_p \|F\|_p$, $1 < p < \infty$, and the proof of the theorem remains unchanged.
2. In Menshov type representation, it is often of interest to control the speed of decrease of the the amplitudes $\{|c_k|\}$, see e.g. [13]. The same is true for the radial representation theorem, see [8]. We wish to pursue this direction with theorem 4. Certainly the condition $\{c_k\} \in l_2$ cannot be achieved here. But one can get quite close, in a sense. Namely, either of the following conditions can be added to the formulation of theorem 4.
 - (a) $\{c_k\} \in l_p \quad \forall p > 2$
 - (b) $\sum |c_k|^2 w(k) < \infty$ for any pre-given positive weight $w(k) \searrow 0$.

The proof requires minor modifications. For example, let us illustrate them for condition (a). The block structure of the “special products” of section 2.2, $F \cdot G_{[r]}$ for $r > 2 \deg F$, implies that

$$\|\widehat{F \cdot G_{[r]}}\|_p = \|\widehat{F}\|_p \cdot \|\widehat{G}\|_p \quad (59)$$

Using that, a direct inspection of the proof of theorem 4 shows that it is enough, given $p > 2$ to replace condition (i) in lemma 4.1 with the stronger (i)' $\|\widehat{Q}\|_p < \epsilon$.

This, in turn, comes from the following estimate for the triangle function

$$\|\widehat{\tau_h}\|_p^p = O(h^{p-1}) \quad .$$

Which gives

$$\|\widehat{Q_s}\|_p = \|\widehat{T^s(F)}\|_p \cdot \|\widehat{G_{[N_s]}}\|_p \leq \|\widehat{\tau_{2\pi/K}}\|_p \cdot \|\widehat{G}\|_p = O\left(K^{\frac{1-p}{p}}\right) \cdot C(\epsilon)$$

and the separation of spectra gives

$$\|\widehat{Q}\|_p^p = \sum_{s=1}^K \|\widehat{Q_s}\|_p^p = O(K^{-p}) \cdot C(\epsilon)$$

and replacing (46) with a suitable sufficiently small K , we get (i)'.

4.4. Representation of infinity. In [3], Menshov proved that for convergence in measure one can extend the class of “representable functions” to include ones taking infinite values. It is natural to formulate this result for real functions. Let f be a measurable function from $\mathbb{T}$ into $\mathbb{R} \cup \{\pm\infty\}$. Menshov’s result says that any such f can be expanded to a real trigonometric series:

$$f(t) = \sum_{k \in \mathbb{Z}} d(k) e^{ikt} \quad d(-k) = \overline{d(k)} \quad (60)$$

converging in measure. Theorem 3 admits also functions as above, and thus gives a direct improvement of Menshov’s result. More precisely the following proposition is true:

Theorem 3'. *Any f as above can be represented by*

$$f(t) = \sum_{k>0} c(k) e^{ikt} \quad (61)$$

where the series converges in measure.

Convergence here means that the real and imaginary parts of the series converge respectively to f and 0 in measure.

We first mention that having (61) one immediately gets the “real” expansion (60) by taking $d(k)$ to be $\frac{1}{2}c(k)$ for $k > 0$ and $\frac{1}{2}\overline{c(k)}$ for $k < 0$. To get (61) we denote by A , B^+ , B^- the sets where f takes finite, $+\infty$ and $-\infty$ values, respectively, and define

$$f_n := \begin{cases} f & \text{on } A \\ n & \text{on } B^+ \\ -n & \text{on } B^- \end{cases} .$$

Now, keeping conditions (i) and (iii) in 4.3 unchanged, we replace f by f_n in (ii) (and in (53)) and replace condition (iv) by these two:

$$(iv)_1 \quad \max_k \|S_k(P_n)\|_{L^2(E_n \cap E_{n-1} \cap A)} < C 2^{-n}$$

$$(iv)_2 \max_k \|S_k(P_n)\|_{L^2(E_n \cap E_{n-1} \cap (B^+ \cup B^-))} < C$$

Repeating the arguments in 4.3 literally one constructs polynomials $\{P_n\}$ satisfying the modified conditions. It is easy to see that these conditions imply that the series (61) yielded by $\sum_{k>0} P_k$ converges to f in measure.

5. POSITIVE SPARSE SPECTRA

5.1. The aim of this section is to improve the results of the previous one, showing that only relatively “small” parts of $\mathbb{Z}^+$ are needed. For brevity, we shall discuss only convergence in measure, rather than asymptotic L^p , and only finite functions.

Definition 3. A set Λ of integers is a *Menshov spectrum in measure* if every $f \in L^0(\mathbb{T})$ admits a representation

$$f(t) = \sum_{k \in \Lambda} c_k e^{ikx} \equiv \lim_{N \rightarrow \infty} \sum_{k \in \Lambda, |k| \leq N} c_k e^{ikx}$$

converging in measure.

We shall prove the following analogues of the results of section 3:

Theorem 5. *Given a positive sequence $\epsilon(n) = o(1)$ as $n \rightarrow \infty$, one can define a Menshov spectrum in measure $\Lambda \subset \mathbb{Z}^+$ such that*

$$\frac{\lambda(n+1)}{\lambda(n)} > 1 + \epsilon(n) \quad n = 1, 2, \dots \quad (62)$$

Theorem 6. *If a set $\Lambda \subset \mathbb{Z}^+$ contains arbitrarily long segments then it is a Menshov spectrum in measure.*

Theorem 7. *For any sequence $w(k) \rightarrow \infty$ as $k \rightarrow \infty$ one can construct a Menshov spectrum in measure Λ ,*

$$\Lambda = \{k^2 + o(w(k))\} \quad .$$

5.2. **The blocks** $D(s, a)$. The equivalent of the blocks $B(s, a)$ from the proof of theorem 1 will be denoted by $D(s, a)$ and defined simply by

$$D(s, a) := B_1^+(s, (2s)^{2s+2}a) + B_2(s, a)$$

where B_1^+ and B_2 are from the definition of $B(s, a)$. Of course, $D(s, a) \subset \mathbb{Z}^+$. The substitute for lemma 3.2 is the following:

Lemma 5.1. *For every $\epsilon > 0$ and $f \in L^0$ there exists an $S = S(f, \epsilon)$ with the following property. Given $s > S$ and $a \in \mathbb{N}$ one may construct a trigonometric polynomial P satisfying*

- (i) $\|f - P\|_0 < \epsilon$;
- (ii) $\text{spec } P \subset D(s, a)$;
- (iii) *For any n , $\mathbf{m}\{t : |S_n(P; t)| > 2|f(t)| + \epsilon\} < \epsilon$.*

Proof. The proof of this lemma is similar to that of lemma 3.2, replacing the use of lemma 2.1 with lemma 4.1, so we will describe it briefly.

First, approximate f by a polynomial P_1 satisfying

$$\|f - P_1\| < \epsilon_1 := \frac{1}{3}\epsilon \quad (63)$$

then use lemma 2.2 to get an analytic polynomial Q_2 satisfying

$$\|Q_2 - 1\|_0 < \epsilon_2 := \frac{\epsilon}{6 \max\{\|\widehat{P_1}\|_1, \deg P_1\} + 3} \quad . \quad (64)$$

Now use lemma 4.1 with

$$\epsilon_3 := \frac{\epsilon}{6\|\widehat{P_1}\|_1\|\widehat{Q_2}\|_1 + 3} \quad (65)$$

to get an analytic Q_3 satisfying

$$\|\widehat{Q_3}\|_\infty \leq \epsilon_3; \quad (66)$$

$$\mathbf{m}\{t : |S_n(Q_3; t)| > 2\} < \epsilon_3 \quad \forall n; \quad (67)$$

$$\|Q_3\|_0 < \epsilon_3 \quad .$$

Set

$$S(f, \epsilon) := \max\{\deg P_1, \deg Q_2, \deg Q_3\} \quad .$$

Fix some $s > S$ and any integer a . Defining, as in (26)

$$\begin{aligned} P_2 &:= \sum_{|k| \leq \deg P_1} \widehat{P_1}(k) e^{ikt} \cdot (Q_2)_{[p(k)]} \\ p(k) &:= a(2s)^{k+s} \end{aligned} \quad (68)$$

we will have $\text{spec } P_2 \subset B_2(s, a)$.

The same estimate as in (28) gives

$$\|P_2 - f\|_0 < \frac{2}{3}\epsilon \quad . \quad (69)$$

Finally, define

$$P \equiv P_3 = (Q_3)_{[p(s+2)]} P_2 \quad .$$

The fact that Q_3 is analytic gives that $\text{spec } (Q_3)_{[p(s+2)]} \subset B_1^+(s, p(s+2))$, which implies (ii). As in lemma 3.2, we have

$$\mathbf{m}\{x : |P - P_2| > \frac{1}{3}\epsilon\} \leq \mathbf{m}\left\{t : |1 - Q_3| > \frac{\epsilon}{3\|\widehat{P_2}\|_\infty}\right\} \quad ,$$

$$\|P_2\|_\infty \leq \|\widehat{P_2}\|_1 \leq \|\widehat{P_1}\|_1 \|\widehat{Q_2}\|_1 \quad (70)$$

so

$$\mathbf{m}\{t : |P - P_2| > \frac{1}{3}\epsilon\} \leq \mathbf{m}\{t : |1 - Q_3| > \epsilon_3\} < \frac{1}{3}\epsilon \quad . \quad (71)$$

Summing (69) and (71) gives (i). To estimate $S_n(P)$ use (31) to write, as in section 2.2, $n = r \cdot p(s+2) + l$ and get

$$S_n(P; t) \leq |S_r(Q_3; p(s+2)t)| \cdot |P_2(t)| + 2\|\widehat{Q_3}\|_\infty \|\widehat{P_2}\|_1$$

as before, estimate $\|\widehat{P_2}\|_1$ by (70). Now (67) and (65) give

$$S_n(P; t) \leq 2|P_2(t)| + \frac{1}{3}\epsilon \quad .$$

outside a set of measure $\epsilon_3 < \frac{1}{3}\epsilon$, and remembering (69), the lemma is proved. $\square$

Lemma 5.1 proves theorem 5 in much the same way as for theorem 1.

5.3. “Analytic” Riesz products. Passing to the proofs of theorems 6 and 7 we make the following remark. In the “squares” theorem of section 3, given a trigonometric polynomial, we used multiplication with a Riesz product to localize the spectrum in a corresponding block of high frequencies and the estimate (42) provided the necessary control of partial sums. In turn, that estimate came essentially from the inequality

$$\int_{\mathbb{T}} \log(1 - \cos t) dm < 0 \quad .$$

Now only the positive part of the spectrum is available, so Riesz products should be replaced by its “analytic” counterpart

$$q_n(t) := \prod_{k \leq n} (1 - e^{i\nu(k)t}) \quad . \quad (72)$$

However,

$$\int_{\mathbb{T}} \log |1 - e^{it}| = 0$$

and the sequence $\{|q_n|\}$ indeed does not tend to zero. But it repeatedly returns close to zero for almost every t . Fortunately, this weaker property is enough to manage the localization of spectrum with a simultaneous control of the partial sums, corresponding to convergence in measure.

Lemma 5.2. *There exists numbers L_k such that for every $\{\nu_k\} \subset \mathbb{Z}$ satisfying*

$$\frac{\nu_k}{\nu_{k-1}} > L_k \quad (73)$$

one has

$$\liminf_{N \rightarrow \infty} \prod_{k=1}^N |1 - e^{i\nu_k t}| = 0 \quad \text{a.e.} \quad (74)$$

Proof. This is equivalent to the following quality

$$\liminf_{N \rightarrow \infty} \sum_{k=1}^N \log |1 - e^{i\nu_k t}| = -\infty \quad \text{a.e.} \quad (75)$$

This is a direct consequence of a well known principle that sparse subsequences of a system $\{\varphi(\nu t)\}$ inherit properties of independent variables, and in our case, that the sum

$$\sum_{k=1}^N \varphi(\nu_k t)$$

behaves like a random walk for a sufficiently fast growing ν_k . We use the following version of this fact, which can be found (in a more general form) in the paper of Gaposhkin [7] (corollary 1): if $\int_{\mathbb{T}} \varphi dm = 0$, $\|\varphi\|_{L^2(\mathbb{T})} = 1$ and

$$\sum_{j < k} \omega_2 \left(\frac{n_j}{n_k}; \varphi \right) = o(1), \quad \sum_{j > k} \omega_2 \left(\frac{n_k}{n_j}; \varphi \right) = o(1) \quad (76)$$

where ω_2 is the module of continuity of φ in the space L^2 , then for every set $E \subset \mathbb{T}$, $mE > 0$,

$$\mathbf{m} \left\{ t \in E : \frac{1}{\sqrt{N}} \sum_{k=1}^N \varphi(\nu_k t) < y \right\} \rightarrow \mathbf{m}E \cdot \frac{1}{\sqrt{2\pi}} \int_{-\infty}^y e^{-t^2/2} dt, \quad N \rightarrow \infty \quad (77)$$

Taking φ to be $\log|1 - e^{it}|$ (after a suitable normalization) one can see that for L_k growing sufficiently fast, (73) implies (76). If (75) fails on a set E of positive measure we get an immediate contradiction to (77) e.g. for $y = 0$. $\square$

Remark. As before, we shall need a rough estimate from below,

$$\left(\frac{3}{4}\right)^n < \prod_{k=1}^n |1 - e^{i\nu_k t}| \quad \forall n > K_1(t) \quad (78)$$

where, as in the proof of theorem 2, here and below $K_j(t)$ are measurable functions $\mathbb{T} \rightarrow \mathbb{N}$ defined almost everywhere. This estimate can be achieved exactly as in lemma 3.4.

5.4. The main lemma. In this section, we shall combine (74) with stopping time techniques, to prove an analogue of lemma 3.3, lemma 5.4 below. Let us start with a definition:

Definition 4. For $s, a, \nu \in \mathbb{Z}^+$ we define

$$D(s, a, \nu) = \nu + D(s, a)$$

and call a set Λ a “ D -set” if one has a sequence $D(s_k, a_k, \nu_k) \subset \Lambda$ with s_k and ν_k tending to ∞ .

Lemma 5.3. *Let $\Lambda \subset \mathbb{Z}^+$ be a D -set; $f \in L^0(\mathbb{T})$ be any function vanishing outside of an interval I ; and $\epsilon > 0$ be some number. Then there exists a polynomial P with the following properties:*

- (i) $\|P - f\|_0 < \epsilon$;
- (ii) $\text{spec } P \subset \Lambda$;
- (iii) For any $n \in \mathbb{Z}^+$,

$$\mathbf{m}\{t \notin I : |S_n(P; t)| > \epsilon\} < \epsilon \quad .$$

Proof. 1. We shall construct inductively a sequence of polynomials P_k using the following procedure:

$$T_k := f - \sum_{l=0}^{k-1} P_l \quad (79)$$

$$R_k(t) := \begin{cases} T_k(t) & |T_l(t)| > \frac{1}{2}\epsilon \forall l \leq k \text{ and } t \in I \\ 0 & \text{otherwise} \end{cases} \quad (80)$$

We now use lemma 5.1 for the function R_k and the parameter $\epsilon 2^{-k-2}$. This gives us some number $S = S(R_k, \epsilon 2^{-k-2})$. let L_k be numbers from lemma 5.2 and choose a_k, ν_k and s_k to satisfy

$$D(s_k, a_k, \nu_k) \subset \Lambda \quad (81)$$

$$\nu_k > L_k \nu_{k-1} \quad (82)$$

$$s_k > S \quad (83)$$

Returning to lemma 5.1, (83) allows us to define a polynomial P'_k satisfying:

$$\text{spec } P'_k \subset D(s_k, a_k) \quad (84)$$

$$\|R_k - P'_k\|_0 < \epsilon 2^{-k-2} \quad (85)$$

and for any n ,

$$\mathbf{m}\{t : |S_n(P'_k; t)| > 2|R_k(t)| + \epsilon 2^{-k-2}\} < \epsilon 2^{-k-2} \quad (86)$$

Finally, we define

$$P_k := e^{i\nu_k t} \cdot P'_k \quad . \quad (87)$$

So, the above process is an inductive definition of sequences T_k , R_k , s_k , a_k , ν_k , P'_k and P_k satisfying (79)-(87).

2. First we claim

$$\|T_k\|_0 < \epsilon \quad \forall k > K(\epsilon) \quad (88)$$

To see this, collect (80), (85) and (87) and get the following for T_k :

$$T_{k+1}(t) = \begin{cases} T_k(t)(1 - e^{i\nu_k t}) + r_k(t) & |T_l(t)| > \frac{1}{2}\epsilon \quad \forall l \leq k \text{ and } t \in I \\ T_k(t) + r_k(t) & \text{otherwise} \end{cases} \quad (89)$$

with

$$\|r_k\|_0 < \epsilon 2^{-k-2} \quad (90)$$

In particular,

$$|r_k(t)| < 2^{-k-2} \quad \forall k > K_2(t) \quad \text{a.e.} \quad (91)$$

Denoting

$$q_n := \prod_{k=1}^n (1 - e^{i\nu_k t}) \quad ,$$

we have (78) and (74) (remember (82)) i.e.

$$|q_n| > \left(\frac{3}{4}\right)^n \quad \forall n > K_1(t); \quad (92)$$

$$\liminf_{n \rightarrow \infty} |q_n(t)| = 0 \quad \text{a.e.} \quad (93)$$

Set:

$$V_\epsilon := \{t \in I : |T_k(t)| > \frac{1}{2}\epsilon \quad \forall k \in \mathbb{N}\} \quad (94)$$

i.e. the set where T_k never “stabilizes”. Using (89), (91) and (93) we have for almost every $t \in V_\epsilon$ and $k > k_1 > \max\{K_1(t), K_2(t)\}$,

$$\begin{aligned} \left| T_{k+1}(t) - T_{k_1}(t) \prod_{l=k_1}^k (1 - e^{i\nu_l t}) \right| &\leq \sum_{l=k_1}^k 2^{-l-2} \prod_{j=l+1}^k |1 - e^{i\nu_j t}| \\ &< \sum_{l \leq k} 2^{-l-2} \left(\frac{3}{4}\right)^l \cdot |q_k(t)| \end{aligned}$$

so

$$\left| T_{k+1}(t) - \frac{T_{k_1}(t)}{q_{k_1-1}(t)} q_k(t) \right| < C |q_k(t)|$$

contrasting this with (92) and (94) we conclude

$$\mathbf{m} V_\epsilon = 0 \quad . \quad (95)$$

Now, (95) gives that for some $K_3(t)$,

$$T_{k+1}(t) = T_k(t) + r_k(t) \quad \forall k \geq K_3(t)$$

and

$$|T_{K_4(t)}| \leq \frac{1}{2}\epsilon$$

Choosing $K(\epsilon)$ sufficiently large to have

$$\mathbf{m} \{t : K_4(t) > K(\epsilon)\} < \frac{1}{2}\epsilon$$

and using (90), we get (88).

3. Let

$$P := \sum_{k=0}^{K(\epsilon)} P_k \quad .$$

(88) and (79) give (i). (81), (84), and (87) give (ii). To see (iii), note that

$$S_n(P_k) = \begin{cases} e^{i\nu_k t} \cdot S_{n-\nu_k}(P'_k) & \forall n \geq \nu_k \\ 0 & \text{otherwise,} \end{cases}$$

(86) means that

$$\mathbf{m} \{t : |S_n(P_k; t)| > 2|R_k(t)| + \epsilon 2^{-k-2}\} < \epsilon 2^{-k-2} \quad . \quad (96)$$

Since $t \notin I \Rightarrow R_k(t) = 0$, summing up the last inequality over k we get (iii). $\square$

Lemma 5.4. *Any D -set is a Menshov spectrum in measure.*

Proof. Let $\Lambda \subset \mathbb{Z}^+$ be a D -set. Let $f \in L^0(\mathbb{T})$ be any function. Take a sequence of intervals $\{I_k\}$ with

$$|I_k| \rightarrow 0$$

which cover each point of the circle infinitely many times. We shall construct inductively a sequence of polynomials P_k using the following procedure. Define

$$R_k := \mathbf{1}_{I_k} \cdot \left(f - \sum_{l=0}^{k-1} P_l \right)$$

and use lemma 5.3 with the data

$$\Lambda_k := \Lambda \cap [\deg P_{k-1}, \infty)$$

(which is clearly a D -set), R_k , I_k and $\epsilon = 2^{-k}$. We get a polynomial P_k which satisfies:

$$\begin{aligned} \text{spec } P_k &\subset \Lambda_k \subset \Lambda \\ \|P_k - R_k\|_0 &< 2^{-k} \end{aligned} \quad (97)$$

and for any $n \in \mathbb{N}$,

$$\mathbf{m} \{t \notin I_k : |S_n(P_k; t)| > 2^{-k}\} < 2^{-k} \quad . \quad (98)$$

The sum of the P_k 's, written as a trigonometric series will prove the lemma. As it is clearly supported on Λ , we need only show that it converges to f in measure. One can easily see that (97) and the fact that the I_k 's cover $\mathbb{T}$ infinitely many times implies that

$$\sum_{k=0}^{\infty} P_k(t) = f(t) \quad \text{a.e.}$$

As the P_k 's follow each other, we write

$$P_k = \sum_{n=\deg P_{k-1}+1}^{\deg P_k} c_n e^{int}$$

and use (98), written as

$$\max_n \|S_n(P_k)\|_0 < 2^{-k} + |I_k| \rightarrow 0 \quad k \rightarrow \infty$$

to get that $\sum_{n \in \Lambda} c_n e^{int} = f(t)$, in measure. $\square$

5.5. Theorem 6 follows from this lemma immediately while theorem 7 is derived in much the same way that theorem 2 follows from lemma 3.5.

Finally, we mention that theorems 5 and 7 are sharp in the same sense that theorems 1 and 2 respectively are. Theorem 5 is sharp for exactly the same reasons as theorem 1; and since proposition 3.7 clearly holds (with an identical proof) for Menshov spectra in measure, we may conclude the sharpness of theorem 7 using proposition 3.8.
